A liquid plug moving in an annular pipe—Flow analysis

Yadi Cao and Ri Li

School of Engineering, University of British Columbia, Kelowna, British Columbia V1V 1V7, Canada

(Received 29 July 2018; accepted 3 September 2018; published online 18 September 2018)

The flow in a liquid plug moving in an annular pipe is analytically solved. The interaction with the two concentric walls of the annular pipe results in two toroidal vortexes within the concentric plug. Focus is put on long plugs with aspect ratio $\beta > 2$, which have vortex circulation flow rates and volume ratio independent of the plug length. Based on the analytical results, correlations are derived for the circulation flow rates of the plug and each vortex and for the volume ratio of the two vortexes. Correlations are also developed for evaluating the radial transport of the plug flow. The friction factor for concentric plugs is a function of the aspect ratio and the radius ratio. For very long plugs with $\beta \gg 1$, the friction factor approaches that of the fully developed continuous flow in the annular pipe. Published by AIP Publishing. https://doi.org/10.1063/1.5050258

I. INTRODUCTION

With the rapid development of microelectronics, microreactors, and micro-electro-mechanical systems (MEMS), the scale of these devices shrinks dramatically, and microfluidics has drawn much attention in recent years. Among all kinds of microfluidics, the hydrodynamics of plug flows is of interest due to their applications in environmental detection, chemical reaction, digital flow, and drug delivery. Comparing to continuous flows, the most significant feature of plug flows is the internal circulation, which can enhance transport processes such as mass and heat transfers.

Generally, there are two categories of plug flows. One category is the liquid-liquid plug flow, while the other category is the gas-liquid plug flow. Most previous studies in the latter category put focus on liquid plugs. Gas-liquid plug flows are common unless more than one liquid flows are required in some specific applications, which then form liquid-liquid plug flows. The present study belongs to the category of gas-liquid plug flows, and the following discussion will be on gas-liquid plug flows only.
Gas-liquid plug flows have been studied experimentally and theoretically. On the experimental side, gas-liquid plug flows have been investigated using non-intrusive methods such as fluorescence and micro PIV (particle imaging velocimetry), and most of the experimental work was restricted to straight and slit channels. On the theoretical side, an analytical approach based on the Stokes flow was taken to solve the gas-liquid flow in a 2-D domain. The flow field is constructed by solving a 4th-order PDE (partial differential equation). This method has been proved effective and convenient for plug flows in channels with different shapes, such as 2-D slit channels, curved channels, and circular channels.

Despite varied cross section shapes, channels that have been used for plug flows are single-walled in that the cross section of the channel is one closed curve. However, the annular channel is different as it has two separate walls. Annular channels are commonly seen in many applications, and one major application is the concentric tube (tube-in-tube) heat exchanger. There has been much attention to annular flows. Studies have been conducted to investigate one liquid flow or two flows in annular channels, very limited work has been reported. The present work is dedicated to the gas-liquid plug flow in annular channels.

The liquid plug is considered incompressible, and the stream function for this axisymmetric flow is

$$\hat{u}_r = \frac{1}{\hat{r}} \frac{\partial \hat{\psi}}{\partial \hat{r}}; \quad \hat{u}_z = -\frac{1}{\hat{r}} \frac{\partial \hat{\psi}}{\partial \hat{z}}.$$
The non-dimensional stream function \( \hat{\psi} \) and the dimensional stream function \( \psi \) are related by

\[
\hat{\psi} \equiv \frac{\psi}{\rho_0 U}.
\]

Regarding the liquid plug, we further assume that the friction term in Eq. (3) is dominant over the inertia term. To satisfy the assumption, it requires

\[
\frac{1^2}{1 - \eta} \ll \frac{1}{\text{Re}(1 - \eta)^2},
\]

which gives

\[
\text{Re}(1 - \eta) \ll 1.
\]

With Eq. (11) being satisfied, Eq. (3) reduces to the Stokes equation given by

\[
\hat{\nabla} \cdot \hat{\psi} = \frac{1}{\text{Re}} \hat{\nabla}^2 \hat{\psi}.
\]

By taking curl of Eq. (12) and substituting Eq. (8) into Eq. (12), we have a 4th-order PDE of the stream function, which is

\[
\hat{P}_4 \hat{\psi} = \left( \frac{\partial^2}{\partial \xi^2} + \frac{\partial^2}{\partial \eta^2} - \frac{1}{\hat{r}} \frac{\partial}{\partial \hat{r}} \right) \left( \frac{\partial^2}{\partial \xi^2} + \frac{\partial^2}{\partial \eta^2} - \frac{1}{\hat{r}} \frac{\partial}{\partial \hat{r}} \right) \hat{\psi} = 0.
\]

For this 4th-order differential equation, two boundary conditions can be obtained from Eq. (4), which are

\[
\frac{1}{\hat{r}} \frac{\partial \hat{\psi}}{\partial \hat{r}} \bigg|_{\hat{r}=\eta} = \frac{1}{\hat{r}} \frac{\partial \hat{\psi}}{\partial \hat{r}} \bigg|_{\hat{r}=1} = -1.
\]

Equations (5) and (6) indicate that all the boundary streamlines have a constant stream function value, which, for convenience, is written as

\[
\hat{\psi}(\hat{z}, \eta) = \hat{\psi}(\hat{z}, 1) = 0
\]

and

\[
\hat{\psi}(0, \hat{r}) = \hat{\psi}(\hat{l}, \hat{r}) = 0.
\]

Equation (7) provides another two boundary conditions, which are

\[
\frac{\partial^2 \hat{\psi}}{\partial \xi^2} \bigg|_{\xi=0} = \frac{\partial^2 \hat{\psi}}{\partial \eta^2} \bigg|_{\eta=\xi} = 0.
\]

To solve Eq. (13), we consider the Fourier series of the stream function. In view of the boundary conditions at \( \hat{z} = 0 \) and \( \hat{z} = \hat{l} \) defined by Eqs. (16) and (17), the stream function can be written in the Fourier series with only sines involved, which is

\[
\hat{\psi} = \sum_{n=1}^{\infty} \hat{\psi}_n = \sum_{n=1}^{\infty} g_n \sin \left( \frac{n \pi \hat{z}}{\hat{l}} \right).
\]

The Fourier coefficients \( g_n \) are given by

\[
g_n = \frac{2}{\hat{l}} \int_0^{\hat{l}} \hat{\psi} \sin \left( \frac{n \pi \hat{z}}{\hat{l}} \right) d\hat{z} = g_n(\hat{r}),
\]

which is a function of \( \hat{r} \) only.

Substituting Eq. (18) into Eq. (12) gives

\[
\left( \frac{d^2}{d\hat{r}^2} - \frac{1}{\hat{r}} \frac{d}{d\hat{r}} - \alpha_n^2 \right) \left( \frac{d^2}{d\hat{r}^2} - \frac{1}{\hat{r}} \frac{d}{d\hat{r}} - \alpha_n^2 \right) g_n = 0,
\]

where \( \alpha_n = n\pi / \hat{l} \) is the eigenvalue. Four boundary conditions are needed for solving Eq. (20). Two boundary conditions can be derived from Eq. (14), which are

\[
\frac{dg_n}{d\hat{r}} \bigg|_{\eta=\hat{r}} = \frac{dg_n}{d\hat{r}} \bigg|_{\hat{r}=1} = -\frac{2\eta}{l} \left[ 1 - (-1)^n \right].
\]

Another two boundary conditions are from Eq. (15), which are

\[
g_n(\eta) = g_n(1) = 0.
\]

The solution of Eq. (20) is

\[
g_n = A_n \hat{r}^2 I_2(\alpha_n \hat{r}) + B_n I_0(\alpha_n \hat{r}) + C_n \hat{r}^2 K_2(\alpha_n \hat{r}) + D_n \hat{r} K_1(\alpha_n \hat{r}).
\]

Here \( I_1 \) and \( I_2 \) are the first and second order of the first-kind modified Bessel functions, respectively. And \( K_1 \) and \( K_2 \) are the first and second order of the second-kind modified Bessel functions, respectively. Equation (23) can also be written based on the zeroth and first-order functions. The coefficients, \( A_n, B_n, C_n, \) and \( D_n, \) should be determined by applying the four boundary conditions given by Eqs. (21) and (22). This can be performed by solving

\[
\begin{pmatrix}
\eta I_2(\alpha_n \eta) & I_1(\alpha_n \eta) & K_2(\alpha_n \eta) & K_1(\alpha_n \eta) \\
I_2(\alpha_n) & I_1(\alpha_n) & K_2(\alpha_n) & K_1(\alpha_n) \\
\eta I_1(\alpha_n \eta) & I_0(\alpha_n \eta) & -\eta K_1(\alpha_n \eta) & -K_0(\alpha_n \eta) \\
I_1(\alpha_n) & I_0(\alpha_n) & -K_1(\alpha_n) & -K_0(\alpha_n)
\end{pmatrix}
\begin{pmatrix}
A_n \\
B_n \\
C_n \\
D_n
\end{pmatrix}
= \begin{pmatrix}
0 \\
0 \\
-\frac{2\eta}{l} \left[ 1 - (-1)^n \right] \\
-\frac{2\eta}{l} \left[ 1 - (-1)^n \right]
\end{pmatrix},
\]

where Cramer’s rule has been used. Clearly, \( A_n, B_n, C_n, \) and \( D_n \) are zero if \( n \) is even.

Finally, the analytical solution of the stream function is

\[
\hat{\psi}(\hat{z}, \hat{r}) = \sum_{n=1,3,5\ldots}^{\infty} [A_n \hat{r}^2 I_2(\alpha_n \hat{r}) + B_n I_0(\alpha_n \hat{r}) + C_n \hat{r}^2 K_2(\alpha_n \hat{r}) + D_n \hat{r} K_1(\alpha_n \hat{r})] \sin(n \pi \hat{z}).
\]

Substituting Eq. (25) into Eq. (8) gives the velocity solutions, which are

\[
\hat{u}_z(\hat{z}, \hat{r}) = \sum_{n=1,3,5\ldots}^{\infty} -\alpha_n [A_n \hat{r} I_1(\alpha_n \hat{r}) + B_n I_0(\alpha_n \hat{r}) - C_n \hat{r} K_1(\alpha_n \hat{r}) - D_n \hat{r} K_0(\alpha_n \hat{r})] \sin(n \pi \hat{z}),
\]

\[
\hat{u}_t(\hat{z}, \hat{r}) = \sum_{n=1,3,5\ldots}^{\infty} -\alpha_n [A_n \hat{r} I_1(\alpha_n \hat{r}) + B_n I_0(\alpha_n \hat{r}) + C_n \hat{r} K_2(\alpha_n \hat{r}) + D_n \hat{r} K_1(\alpha_n \hat{r})] \cos(n \pi \hat{z}).
\]

The pressure solution can be obtained by applying Eqs. (26) and (27) to Eq. (12) with the given pressure boundary conditions and the Reynolds number \( Re \). The pressure drop and friction factor will be discussed in Sec. V.
III. CIRCULATION AND VORTEXES

The stream function given by Eq. (25) is plotted in Fig. 2 for three plugs, which have varied values of $\eta$ and $\hat{l}$. Two toroidal vortexes are formed inside the plug: the one close to the outer wall is called the outer vortex, and the one close to the inner wall is called the inner vortex. The inner vortex is smaller than the outer vortex. As $\eta$ increases, the difference diminishes. The two vortexes are in contact at $\hat{r} = \hat{r}_c$, where the streamline $\hat{\psi} = 0$. The outer vortex is located at $\hat{r} > \hat{r}_c$, where $\hat{\psi} > 0$. The maximum of $\hat{\psi}$ is denoted by $\hat{\psi}_o$, which is the non-dimensional circulation flow rate of the outer vortex, in short called the outer circulation rate. The inner vortex is located at $\hat{r} < \hat{r}_c$, where $\hat{\psi} < 0$. The minimum of $\hat{\psi}$ is denoted by $\hat{\psi}_i$, and the circulation flow rate of the inner vortex is $|\hat{\psi}_i|$, in short called the inner circulation rate.

The range of the stream function, $\hat{\psi}_o - \hat{\psi}_i$, is the circulation flow rate of the entire plug, in short called the plug circulation rate. Figure 3(a) shows that the plug circulation rate increases with the length $\hat{l}$ when $\hat{l}$ is small and eventually becomes independent of $\hat{l}$. The inner radius $\eta$ shows more effect on the circulation flow rate. As $\eta$ increases from 0 to 1, the flow rate reduces toward zero. The two vortexes are compared using $|\hat{\psi}_i/\hat{\psi}_o|$, which is plotted in Fig. 3(b). The ratio decreases with increasing $\hat{l}$ for short plugs, and it becomes independent of $\hat{l}$ for long plugs. When $\eta$ is small, the plug circulation is dominated by the outer vortex. As $\eta$ increases, the difference of the circulation rate between the two vortexes decreases.

The two vortexes border at $\hat{r} = \hat{r}_c$, which can be determined from the volume ratio of the two vortexes using

$$\frac{\hat{V}_i}{\hat{V}_o} = \frac{\hat{r}_c^2 - \eta^2}{1 - \hat{r}_c^2}, \quad (28)$$

where $\hat{V}_i$ and $\hat{V}_o$ are the non-dimensional volumes of the inner vortex and outer vortex, respectively, which have been normalized by the volume of the plug. The volume ratio is plotted in Fig. 4, which shows that the inner vortex is always smaller than the outer vortex. For short plugs, the volume ratio decreases with increasing $\hat{l}$, while for long plugs, the volume ratio is independent of $\hat{l}$.

Figures 3 and 4 show that the circulation rates and the volume ratios are dependent on $\hat{l}$ for short plugs but independent of $\hat{l}$ for long plugs. However, the ranges of $\hat{l}$ for the short and long plugs vary with $\eta$. To determine the short and long plugs, we introduce

$$\beta = \frac{l}{r_o - r_i} = \frac{\hat{l}}{1 - \eta}, \quad (29)$$

which is called the aspect ratio. In Fig. 5, the plug circulation rate is plotted versus the aspect ratio. As shown by the inset in Fig. 5, $(\hat{\psi}_o - \hat{\psi}_i)_{max}$ is the circulation rate of long plugs, which is independent of $\hat{l}$. Figure 5 shows that, regardless of

FIG. 2. Streamlines of three plugs: (a) $\eta = 0.1, \hat{l} = 2.7$; (b) $\eta = 0.5, \hat{l} = 1.5$; and (c) $\eta = 0.9, \hat{l} = 0.3$. In the floor-attached frame of reference, the plugs are moving from left to right.
FIG. 3. (a) Plug circulation rate and (b) circulation rate ratio of the inner vortex to the outer vortex.

η, \( \hat{\psi}_o - \hat{\psi}_i \) is within less than 1% difference from \( (\hat{\psi}_o - \hat{\psi}_i)_{\text{max}} \) for \( \beta > 2 \). Similar trends can be observed if the data of the circulation rate ratio in Fig. 3(b) and the data of volume ratio in Fig. 4 are plotted against \( \beta \). Hence, plugs with aspect ratio \( \beta > 2 \) are considered as long plugs.

FIG. 4. Volume ratio of the inner vortex to the outer vortex.

IV. CIRCULATION IN LONG PLUGS (\( \beta > 2 \))

The analysis in this section will focus on long plugs, which have relatively large aspect ratios, i.e., \( \beta > 2 \). To focus on long plugs is mainly because the assumption of flat-ended plugs is reasonable only for long plugs. As shown above, the circulation flow rates and the volume ratio of the two vortexes are dependent on \( \eta \) only. Correlations will be derived in this section.

Equation (25) is applied to long plugs with varied inner radii \( \eta \) and lengths \( \bar{l} \). The inner radius \( \eta \) is varied between 0 and 1, while \( \bar{l} \) is changed accordingly to ensure \( \beta > 2 \). The maxima and minima of the stream function \( \hat{\psi} \) are determined to obtain the circulation flow rates of the outer vortex, the inner vortex, and the plug, which are \( \hat{\psi}_o \), \( |\hat{\psi}_i| \), and \( \hat{\psi}_o - \hat{\psi}_i \), respectively. The three circulation rates are plotted in Fig. 6. The plug circulation

FIG. 5. Plug circulation rate is independent of \( \bar{l} \) for \( \beta > 2 \). Here data points are plotted as lines instead of scattered symbols. The data presented in Fig. 3 are included.

FIG. 6. Plug circulation rate, inner circulation rate, and outer circulation rate of long plugs (\( \beta > 2 \)). Scattered symbols are the data from Eq. (25). Solid lines are plotted using derived correlation equations as indicated.
decreases as \( \eta \) increases. If \( \eta = 1 \) (i.e., \( r_1 = r_o \)), the flow rate is zero as there is no flow area. The inner circulation is zero if \( \eta = 0 \). The relationship of the three circulation rates with \( \eta \) will be derived later.

The two vortexes in long plugs are compared in Fig. 7, where the circulation flow rate ratio \( \hat{\psi}/\hat{\psi}_0 \) and the volume ratio \( V_i/V_o \) are plotted against \( \eta \). The volume ratio of the two vortexes shows a linear relationship with the radius ratio of the plug, which is

\[
V_i/V_o = \eta. \tag{30}
\]

Combining Eqs. (28) and (30) gives the border location of the two vortexes, which is

\[ \hat{r}_c = \eta^{0.5}. \tag{31}\]

Similarly, Fig. 7 shows that the circulation rate ratio of the two vortexes changes with \( \eta \) following

\[ |\hat{\psi}_i/\hat{\psi}_o| = \eta^{1.16}. \tag{32}\]

To further analyze the plug circulation, we introduce the circulation period, denoted by \( \tau \), during which the circulated volume of fluid is equal to the plug volume. For convenience, we use \( \tau^{-1} \), called the circulation frequency. The definition of the circulation frequency is

\[ \tau^{-1} = \frac{2\pi (\hat{\psi}_o - \hat{\psi}_i) r_o^2 U}{\pi (r_o^2 - r_i^2) l}. \tag{33}\]

Applying rearrangement gives the circulation frequency in its non-dimensional form, which is

\[ f^{-1} = \left( \frac{\tau U}{r_o} \right)^{-1} = \frac{2(\hat{\psi}_o - \hat{\psi}_i)}{(1 - \eta^2) l}. \tag{34}\]

The non-dimensional circulation frequency is plotted against the length \( l \) in Fig. 8. Applying curve fitting gives

\[ f^{-1} = 0.1973 l^{-1}. \tag{35}\]

Equation (35) shows that the frequency is inversely proportional to the plug length and that the frequency is independent of the inner radius \( \eta \).

Combining Eqs. (34) and (35) gives the correlation for the plug circulation rate of long plugs, which is

\[ \hat{\psi}_o - \hat{\psi}_i = 0.0986(1 - \eta^2). \tag{36}\]

Combining Eq. (36) and Eq. (32), we obtain the correlation for the outer circulation rate of long plugs, which is

\[ \hat{\psi}_o = \frac{0.0986(1 - \eta^2)}{1 + \eta^{1.16}}. \tag{37}\]

And the correlation for the inner circulation rate of long plugs is

\[ |\hat{\psi}_i| = \frac{0.0986(1 - \eta^2) \eta^{1.16}}{1 + \eta^{1.16}}. \tag{38}\]

Equations (36)–(38) are plotted in Fig. 6. For the inner vortex, Eq. (38) shows good agreement with the data points. For the outer vortex, Eq. (37) agrees well with the data points except for plugs with small inner radius, \( \eta \sim < 0.2 \). As a result, Eq. (36) predicts the plug circulation rate with good accuracy except for small inner radii.

The major difference between the plug flow and the continuous flow in an annular pipe is the circulation flow inside the plug. The circulation results in transport in the radial direction, which does not exist in the fully developed continuous flow. The radial transport can be characterized by

\[ Q' = \frac{\left( \hat{\psi}_o - \hat{\psi}_i \right) r_o^2 U}{l^{1/2}}, \tag{39}\]

which is the plug circulation rate divided by half plug length. Here \( Q' \) is a volumetric flow rate per unit radian of the polar angle and per unit length and is called the radial flux. We further non-dimensionalize Eq. (39) and substitute Eq. (36) into Eq. (39) and get

\[ \hat{Q}' = \frac{Q'}{r_o U} = \frac{2(\hat{\psi}_o - \hat{\psi}_i)}{l^{1/2}} = 0.1973 l^{-1/2}(1 - \eta^2). \tag{40}\]
Equation (40) shows that the radial flux decreases with increasing the plug length and/or increasing the inner radius.

Similar to Eq. (40), the radial flux of the inner vortex can be evaluated using

$$
\hat{Q}_i = 2 |\hat{\psi}_i| = \frac{0.1973(1 - \eta^2)\eta^{1.16}}{(1 + \eta^{1.16})r^2}.
$$

The radial flux of the outer vortex can be evaluated using

$$
\hat{Q}_o = 2 |\hat{\psi}_o| = \frac{0.1973(1 - \eta^2)}{(1 + \eta^{1.16})r^2}.
$$

Equations (40)–(42) are useful for studying transport processes such as heat transfer of the plug flow.

V. Friction Factor

Here we will focus on the viscous friction of the liquid plug and derive the friction factor for concentric plugs. The viscous drag force on a plug moving in an annular pipe is

$$
F = -2\pi\mu \left[ R \int_0^\eta \left( \frac{\partial u_\tau}{\partial \tau} \right) dz \right]_{R=r_i}^{R=r_o}.
$$

Here $R$ is the radial location of the pipe wall. The minus sign on the left indicates that the force is opposite to the plug motion and in the negative $z$ direction (see Fig. 1). Applying force balance to the plug, the pressure drop in the $z$ direction across the plug is

$$
\Delta p = \frac{\Delta \rho}{\rho U^2} = \frac{F}{\pi \left( r_o^2 - r_i^2 \right) \rho U^2}
$$

$$
= -\frac{2}{\text{Re}(1 - \eta^2)} \left[ \hat{R} \int_0^\eta \left( \frac{\partial u_z}{\partial \tau} \right) dz \right]_{\hat{R}=\hat{R}_i}^{\hat{R}=\hat{R}_o}.
$$

The hydraulic diameter of the plug is $D_h = 2(r_o - r_i)$, and the Reynolds number based on the hydraulic diameter is

$$
\text{Re}_{D_h} = \frac{\rho UD_h}{\mu} = 2(1 - \eta) \text{Re},
$$

where the other Reynolds number defined in Eq. (1) has been used. The Darcy friction factor is defined as

$$
f = \frac{-\left( \Delta \rho \right) / D_h}{\rho U^2 / 2} = -\frac{\Delta p}{\beta},
$$

where the definition of the aspect ratio, Eq. (29), has been used. Substituting Eq. (44) into Eq. (46) gives

$$
f \text{Re}_{D_h} = \frac{32}{\beta(1 + \eta)} \sum_{n=1,3,5...}^{\infty} \alpha_n [A_n \hat{R}^2 I_0(\alpha_n \hat{R}) + B_n \hat{K}_0(\alpha_n \hat{R})]
$$

$$
+ C_n \hat{R}^2 K_0(\alpha_n \hat{R}) + D_n \hat{R} K_1(\alpha_n \hat{R})]_{\hat{R}=\hat{R}_i}^{\hat{R}=\hat{R}_o}.
$$

Equation (47) is applied to plugs with varied values of aspect ratio $\beta$ and radius ratio $\eta$, and the results are plotted in Fig. 9. Generally, $f \text{Re}_{D_h}$ decreases with increasing $\beta$ and increases with increasing $\eta$. As $\beta$ becomes big, $f \text{Re}_{D_h}$ approaches a steady value specific for a given $\eta$. 

If a plug is very long, i.e., $\beta \to \infty$, the flow approaches a continuous annulus flow. The solution for a fully developed continuous flow in an annular pipe is

$$
\hat{u}_c = \frac{2 \left( 1 - \hat{r}^2 \right) \ln \hat{r} - 2 \left( 1 - \hat{r}^2 \right) \ln \hat{r}}{(1 - \eta^2) + (1 + \eta^2) \ln \eta - 1}.
$$

In a similar fashion to Eqs. (43)–(47), the friction factor for the continuous annulus flow is

$$
f \text{Re}_{D_h} = \frac{64(1 - \eta^2) \ln \eta}{(1 - \eta^3) + (1 + \eta^2) \ln \eta}.
$$

As shown in Fig. 9, Eq. (49) agrees with the steady values of $f \text{Re}_{D_h}$ for long plugs.

To further compare the friction factor of plug flows with continuous flows, Eq. (47) is plotted versus the radius ratio for long plugs ($\beta = 10$ and 100) in comparison with Eq. (49), as shown in Fig. 10. Plugs with $\beta = 100$ behave like continuous flows as their friction factor values match well with those of the continuous flows. Both Eq. (47) and Eq. (49) also match with other laminar flows in tubes with different cross sections.
Figure 10 shows that as \( \eta \rightarrow 0 \), \( f/Re_{D_h} \) approaches 64, which is for the circular pipe flow. As \( \eta \rightarrow 1 \), \( f/Re_{D_h} \) approaches 96, which is for the flow between two parallel plates.

From the results shown in Figs. 9 and 10, it can be concluded that the flow in a very long plug is the same as the continuous flow. In a continuous annular flow, if we move in the flow direction at a speed equal to the mean flow velocity, we should be able to observe streamlines similar to those shown in Fig. 2, but the observed streamlines are all horizontal and parallel and are infinite in the \( z \) direction.

VI. SUMMARY

The Stokes equation is solved for a liquid plug moving in an annular pipe. By plotting the stream function solution, we observe two toroidal vortices due to the friction on the two concentric walls. It is found that the circulation flow rates and the volume ratio of the two vortices change with the plug length for short plugs and become independent of the plug length for long plugs. It is found that plugs can be considered long if its aspect ratio is larger than 2.

Focus is put on long plugs. The circulation rate ratio and the volume ratio of the two vortices show simple relationships with respect to the inner radius. The circulation frequency is found to be independent of the inner radius. Based on the curve fitting equations, correlations for plug, inner, and outer circulation rates are derived. Furthermore, the radial flux is introduced and its correlations are developed for evaluating the radial transport of the plug flow. The correlations are useful for applications based on plug flows. For example, they can be used for designing plug-flow concentric tube (tube-in-tube) heat exchangers.

The friction factor of the concentric plug is a function of the aspect ratio and radius ratio. When the plug is very long, i.e., \( \beta > 1 \), the plug flow behaves like the continuous flow. When the radius ratio approaches zero or unity, the derived friction factors match with those of the circular pipe flow and the flow between parallel plates.
